2.1 *Cite the difference between atomic mass and atomic weight.*

**Solution**

Atomic mass is the mass of an individual atom, whereas atomic weight is the average (weighted) of the atomic masses of an atom's naturally occurring isotopes.

2.2 *Silicon has three naturally occurring isotopes: 92.23% of $^{28}\text{Si}$, with an atomic weight of 27.9769 amu, 4.68% of $^{29}\text{Si}$, with an atomic weight of 28.9765 amu, and 3.09% of $^{30}\text{Si}$, with an atomic weight of 29.9738 amu. On the basis of these data, confirm that the average atomic weight of Si is 28.0854 amu.*

**Solution**

The average atomic weight of silicon $(A_{\text{Si}})$ is computed by adding fraction-of-occurrence/atomic weight products for the three isotopes—i.e., using Equation 2.2. (Remember: fraction of occurrence is equal to the percent of occurrence divided by 100.) Thus

$$A_{\text{Si}} = f_{^{28}\text{Si}}A_{^{28}\text{Si}} + f_{^{29}\text{Si}}A_{^{29}\text{Si}} + f_{^{30}\text{Si}}A_{^{30}\text{Si}}$$

$$= (0.9223)(27.9769) + (0.0468)(28.9765) + (0.0309)(29.9738) = 28.0854$$
2.3 Zinc has five naturally occurring isotopes: 48.63% of $^{64}$Zn with an atomic weight of 63.929 amu; 27.90% of $^{66}$Zn with an atomic weight of 65.926 amu; 4.10% of $^{67}$Zn with an atomic weight of 66.927 amu; 18.75% of $^{68}$Zn with an atomic weight of 67.925 amu; and 0.62% of $^{70}$Zn with an atomic weight of 69.925 amu. Calculate the average atomic weight of Zn.

Solution

The average atomic weight of zinc $A_{\text{Zn}}$ is computed by adding fraction-of-occurrence—atomic weight products for the five isotopes—i.e., using Equation 2.2. (Remember: fraction of occurrence is equal to the percent of occurrence divided by 100.) Thus

$$A_{\text{Zn}} = f_{64}\text{Zn}A_{64}\text{Zn} + f_{66}\text{Zn}A_{66}\text{Zn} + f_{67}\text{Zn}A_{67}\text{Zn} + f_{68}\text{Zn}A_{68}\text{Zn} + f_{70}\text{Zn}A_{70}\text{Zn}$$

Including data provided in the problem statement we solve for $A_{\text{Zn}}$ as

$$A_{\text{Zn}} = (0.4863)(63.929 \text{ amu}) + (0.2790)(65.926 \text{ amu})$$
$$+ (0.0410)(66.927 \text{ amu}) + (0.1875)(67.925 \text{ amu}) + (0.0062)(69.925)$$

$$= 65.400 \text{ amu}$$

2.4 Indium has two naturally occurring isotopes: $^{113}$In with an atomic weight of 112.904 amu, and $^{115}$In with an atomic weight of 114.904 amu. If the average atomic weight for In is 114.818 amu, calculate the fraction-of-occurrences of these two isotopes.

Solution

The average atomic weight of indium $A_{\text{In}}$ is computed by adding fraction-of-occurrence—atomic weight products for the two isotopes—i.e., using Equation 2.2, or

$$A_{\text{In}} = f_{113}\text{In}A_{113}\text{In} + f_{115}\text{In}A_{115}\text{In}$$
Because there are just two isotopes, the sum of the fracture-of-occurrences will be 1.000; or

\[ f_{113} + f_{115} = 1.000 \]

which means that

\[ f_{113} = 1.000 - f_{115} \]

Substituting into this expression the one noted above for \( f_{113} \), and incorporating the atomic weight values provided in the problem statement yields

\[ 114.818 \text{ amu} = f_{113}A_{113} + f_{115}A_{115} \]

\[ 114.818 \text{ amu} = (1.000 - f_{113})A_{113} + f_{115}A_{115} \]

\[ 114.818 \text{ amu} = (1.000 - f_{113})(112.904 \text{ amu}) + f_{115}(114.904 \text{ amu}) \]

\[ 114.818 \text{ amu} = 112.904 \text{ amu} - f_{115}(112.904 \text{ amu}) + f_{115}(114.904 \text{ amu}) \]

Solving this expression for \( f_{115} \) yields \( f_{115} = 0.957 \). Furthermore, because

\[ f_{113} = 1.000 - f_{115} \]

then

\[ f_{113} = 1.000 - 0.957 = 0.043 \]
2.5 (a) How many grams are there in one amu of a material?

(b) Mole, in the context of this book, is taken in units of gram-mole. On this basis, how many atoms are there in a pound-mole of a substance?

Solution

(a) In order to determine the number of grams in one amu of material, appropriate manipulation of the amu/atom, g/mol, and atom/mol relationships is all that is necessary, as

\[
\frac{\text{amu}}{\text{atom}} \times \frac{\text{g/mol}}{\text{g/amu}} = \frac{6.022 \times 10^{23} \text{ atoms}}{1 \text{ amu/atom}} \times \frac{1 \text{ g/mol}}{6.022 \times 10^{23} \text{ atoms}}
\]

\[
= 1.66 \times 10^{24} \text{ g/amu}
\]

(b) Since there are 453.6 g/lbm,

\[
1 \text{ lb-mol} = (453.6 \text{ g/lbm}) \times (6.022 \times 10^{23} \text{ atoms/g-mol})
\]

\[
= 2.73 \times 10^{26} \text{ atoms/lb-mol}
\]
2.6 (a) Cite two important quantum-mechanical concepts associated with the Bohr model of the atom.
(b) Cite two important additional refinements that resulted from the wave-mechanical atomic model.

Solution

(a) Two important quantum-mechanical concepts associated with the Bohr model of the atom are (1) that electrons are particles moving in discrete orbitals, and (2) electron energy is quantized into shells.

(b) Two important refinements resulting from the wave-mechanical atomic model are (1) that electron position is described in terms of a probability distribution, and (2) electron energy is quantized into both shells and subshells—each electron is characterized by four quantum numbers.
2.7 *Relative to electrons and electron states, what does each of the four quantum numbers specify?*

**Solution**

The *n* quantum number designates the electron shell.

The *l* quantum number designates the electron subshell.

The *m_l* quantum number designates the number of electron states in each electron subshell.

The *m_s* quantum number designates the spin moment on each electron.
2.8 Allowed values for the quantum numbers of electrons are as follows:

\[ n = 1, 2, 3, \ldots \]
\[ l = 0, 1, 2, 3, \ldots, n-1 \]
\[ m_l = 0, \pm 1, \pm 2, \pm 3, \ldots, \pm l \]
\[ m_s = \pm \frac{1}{2} \]

The relationships between \( n \) and the shell designations are noted in Table 2.1. Relative to the subshells,

\( l = 0 \) corresponds to an \( s \) subshell
\( l = 1 \) corresponds to a \( p \) subshell
\( l = 2 \) corresponds to a \( d \) subshell
\( l = 3 \) corresponds to an \( f \) subshell

For the \( K \) shell, the four quantum numbers for each of the two electrons in the \( 1s \) state, in the order of \( nlm_m \), are

\[ \frac{1}{2} \] \( 100(\frac{1}{2}) \) and \( 100(-\frac{1}{2}) \). Write the four quantum numbers for all of the electrons in the \( L \) and \( M \) shells, and note which correspond to the \( s \), \( p \), and \( d \) subshells.

**Answer**

For the \( L \) state, \( n = 2 \), and eight electron states are possible. Possible \( l \) values are 0 and 1, while possible \( m_l \) values are 0 and \( \pm 1 \); and possible \( m_s \) values are \( \pm \frac{1}{2} \). Therefore, for the \( s \) states, the quantum numbers are \( \frac{1}{2} \) \( 200(\frac{1}{2}) \) and \( \frac{1}{2} \) \( 200(-\frac{1}{2}) \). For the \( p \) states, the quantum numbers are \( \frac{1}{2} \) \( 210(\frac{1}{2}) \), \( 210(-\frac{1}{2}) \), \( 211(\frac{1}{2}) \), \( 211(-\frac{1}{2}) \), \( 21(-1)(\frac{1}{2}) \), and \( 21(-1)(-\frac{1}{2}) \).

For the \( M \) state, \( n = 3 \), and 18 states are possible. Possible \( l \) values are 0, 1, and 2; possible \( m_l \) values are 0, \( \pm 1 \), and \( \pm 2 \); and possible \( m_s \) values are \( \pm \frac{1}{2} \). Therefore, for the \( s \) states, the quantum numbers are \( \frac{1}{2} \) \( 300(\frac{1}{2}) \), \( 300(-\frac{1}{2}) \), \( 310(\frac{1}{2}) \), \( 310(-\frac{1}{2}) \), \( 311(\frac{1}{2}) \), \( 311(-\frac{1}{2}) \), and \( 31(-1)(\frac{1}{2}) \); for the \( d \) states they are
are \( \frac{1}{2} 320(\frac{1}{2}) \), \( \frac{1}{2} \), \( \frac{1}{2} \), \( \frac{1}{2} \), \( \frac{1}{2} \), \( \frac{1}{2} \), \( \frac{1}{2} \), \( \frac{1}{2} \), \( \frac{1}{2} \), \( \frac{1}{2} \), \( \frac{1}{2} \), \( \frac{1}{2} \), \( \frac{1}{2} \), and

\[
\frac{1}{2} 32(-1)(-, 32(-1)(-, 322()) , 322(-), 32(-2)(-) , and
\]

\[
\frac{1}{2} 32(-2)(-).
\]

2.9 *Give the electron configurations for the following ions: P\(^{5+}\), P\(^{3-}\), Sn\(^{4+}\), Se\(^{2-}\), I\(^{-}\), and Ni\(^{2+}\).*

**Solution**

The electron configurations for the ions are determined using Table 2.2 (and Figure 2.8).

\( \text{P}^{5+} \): From Table 2.2, the electron configuration for an atom of phosphorus is 1s\(^2\)2s\(^2\)2p\(^6\)3s\(^2\)3p\(^3\). In order to become an ion with a plus five charge, it must lose five electrons—in this case the three 3p and the two 3s. Thus, the electron configuration for a P\(^{5+}\) ion is 1s\(^2\)2s\(^2\)2p\(^6\).

\( \text{P}^{3-} \): From Table 2.2, the electron configuration for an atom of phosphorus is 1s\(^2\)2s\(^2\)2p\(^6\)3s\(^2\)3p\(^3\). In order to become an ion with a minus three charge, it must acquire three electrons—in this case another three 3p. Thus, the electron configuration for a P\(^{3-}\) ion is 1s\(^2\)2s\(^2\)2p\(^6\)3s\(^2\)3p\(^6\).

\( \text{Sn}^{4+} \): From the periodic table, Figure 2.8, the atomic number for tin is 50, which means that it has fifty electrons and an electron configuration of 1s\(^2\)2s\(^2\)2p\(^6\)3s\(^2\)3p\(^6\)3d\(^{10}\)4s\(^2\)4p\(^6\)4d\(^{10}\)5s\(^2\)5p\(^2\). In order to become an ion with a plus four charge, it must lose four electrons—in this case the two 4s and two 5p. Thus, the electron configuration for an Sn\(^{4+}\) ion is 1s\(^2\)2s\(^2\)2p\(^6\)3s\(^2\)3p\(^6\)3d\(^{10}\)4s\(^2\)4p\(^6\)4d\(^{10}\).

\( \text{Se}^{2-} \): From Table 2.2, the electron configuration for an atom of selenium is 1s\(^2\)2s\(^2\)2p\(^6\)3s\(^2\)3p\(^6\)3d\(^{10}\)4s\(^2\)4p\(^4\). In order to become an ion with a minus two charge, it must acquire two electrons—in this case another two 4p. Thus, the electron configuration for an Se\(^{2-}\) ion is 1s\(^2\)2s\(^2\)2p\(^6\)3s\(^2\)3p\(^6\)3d\(^{10}\)4s\(^2\)4p\(^6\).

\( \text{I}^{-} \): From the periodic table, Figure 2.8, the atomic number for iodine is 53, which means that it has fifty three electrons and an electron configuration of 1s\(^2\)2s\(^2\)2p\(^6\)3s\(^2\)3p\(^6\)3d\(^{10}\)4s\(^2\)4p\(^6\)4d\(^{10}\)5s\(^2\)5p\(^5\). In order to become an ion with a minus one charge, it must acquire one electron—in this case another 5p. Thus, the electron configuration for an I\(^{-}\) ion is 1s\(^2\)2s\(^2\)2p\(^6\)3s\(^2\)3p\(^6\)3d\(^{10}\)4s\(^2\)4p\(^6\)4d\(^{10}\)5s\(^2\)5p\(^6\).

\( \text{Ni}^{2+} \): From Table 2.2, the electron configuration for an atom of nickel is 1s\(^2\)2s\(^2\)2p\(^6\)3s\(^2\)3p\(^6\)3d\(^8\)4s\(^2\). In order to become an ion with a plus two charge, it must lose two electrons—in this case the two 4s. Thus, the electron configuration for a Ni\(^{2+}\) ion is 1s\(^2\)2s\(^2\)2p\(^6\)3s\(^2\)3p\(^6\)3d\(^8\).
Potassium iodide (KI) exhibits predominantly ionic bonding. The $K^+$ and $I^-$ ions have electron structures that are identical to which two inert gases?

Solution

The $K^+$ ion is just a potassium atom that has lost one electron; therefore, it has an electron configuration the same as argon (Figure 2.8).

The $I^-$ ion is a iodine atom that has acquired one extra electron; therefore, it has an electron configuration the same as xenon.
2.11 With regard to electron configuration, what do all the elements in Group IIA of the periodic table have in common?

Solution
Each of the elements in Group IIA has two s electrons.
To what group in the periodic table would an element with atomic number 112 belong?

Solution

From the periodic table (Figure 2.8) the element having atomic number 112 would belong to group IIB. According to Figure 2.8, Ds, having an atomic number of 110 lies below Pt in the periodic table and in the right-most column of group VIII. Moving two columns to the right puts element 112 under Hg and in group IIB.

This element has been artificially created and given the name Copernicium with the symbol Cn. It was named after Nicolaus Copernicus, the Polish scientist who proposed that the earth moves around the sun (and not vice versa).
2.13 Without consulting Figure 2.8 or Table 2.2, determine whether each of the following electron configurations is an inert gas, a halogen, an alkali metal, an alkaline earth metal, or a transition metal. Justify your choices.

(a) \(1s^22s^22p^63s^23p^5\)
(b) \(1s^22s^22p^63s^23p^63d^74s^2\)
(c) \(1s^22s^22p^63s^23p^63d^{10}4s^24p^6\)
(d) \(1s^22s^22p^63s^23p^64s^1\)
(e) \(1s^22s^22p^63s^23p^63d^{10}4s^24p^64d^55s^2\)
(f) \(1s^22s^22p^63s^2\)

Solution

(a) The \(1s^22s^22p^63s^23p^5\) electron configuration is that of a halogen because it is one electron deficient from having a filled \(p\) subshell.

(b) The \(1s^22s^22p^63s^23p^63d^74s^2\) electron configuration is that of a transition metal because of an incomplete \(d\) subshell.

(c) The \(1s^22s^22p^63s^23p^63d^{10}4s^24p^6\) electron configuration is that of an inert gas because of filled \(4s\) and \(4p\) subshells.
(d) The $1s^2 2s^2 2p^6 3s^2 3p^6 4s^1$ electron configuration is that of an alkali metal because of a single $s$ electron. (e) The $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6 4d^5 5s^2$ electron configuration is that of a transition metal because of an incomplete $d$ subshell.

(f) The $1s^2 2s^2 2p^6 3s^2$ electron configuration is that of an alkaline earth metal because of two $s$ electrons.

(a) What electron subshell is being filled for the rare earth series of elements on the periodic table?

(b) What electron subshell is being filled for the actinide series?

**Solution**

(a) The $4f$ subshell is being filled for the rare earth series of elements.

(b) The $5f$ subshell is being filled for the actinide series of elements.
Bonding Forces and Energies

2.15 Calculate the force of attraction between a Ca\(^{2+}\) and an O\(^{2-}\) ion whose centers are separated by a distance of 1.25 nm.

Solution

To solve this problem for the force of attraction between these two ions it is necessary to use Equation 2.13, which takes on the form of Equation 2.14 when values of the constants \(e\) and \(\boxed{\text{m}}\) are included—that is

\[
F_A = \frac{(2.31 \times 10^{-28} \text{ N} \cdot \text{m}^2)}{r^2} (Z_1)(Z_2)
\]

If we take ion 1 to be Ca\(^{2+}\) and ion 2 to be O\(^{2-}\), then \(Z_1 = +2\) and \(Z_2 = 2\); also, from the problem statement \(r = 1.25\) nm = 1.25 \(\times\) \(10^{-9}\) m. Thus, using Equation 2.14, we compute the force of attraction between these two ions as follows:

\[
F_A = \frac{(2.31 \times 10^{-28} \text{ N} \cdot \text{m}^2)}{(1.25 \times 10^{-9} \text{ m})^2} (2)(1)
\]
$5.91 \times 10^{-10}$ N
The atomic radii of Mg$^{2+}$ and F$^{\ominus}$ ions are 0.072 and 0.133 nm, respectively.

(a) Calculate the force of attraction between these two ions at their equilibrium interionic separation (i.e., when the ions just touch one another).

(b) What is the force of repulsion at this same separation distance.

Solution

This problem is solved in the same manner as Example Problem 2.2.

(a) The force of attraction $F_A$ is calculated using Equation 2.14 taking the interionic separation $r$ to be $r_0$ the equilibrium separation distance. This value of $r_0$ is the sum of the atomic radii of the Mg$^{2+}$ and F$^{\ominus}$ ions (per Equation 2.15)—that is

\[ r_0 = r_{Mg^{2+}} + r_{F^{-}}. \]

\[ = 0.072 \text{ nm} + 0.133 \text{ nm} = 0.205 \text{ nm} = 0.205 \times 10^{-9} \text{ m} \]

We may now compute $F_A$ using Equation 2.14. If was assume that ion 1 is Mg$^{2+}$ and ion 2 is F$^{\ominus}$ then the respective charges on these ions are $Z_1 = Z_{Mg^{2+}} = +2$, whereas $Z_2 = Z_{F^{-}} = -1$. Therefore, we determine $F_A$ as follows:

\[ F_A = \frac{(2.31 \times 10^{-28} \text{ N} \cdot \text{m}^2) \left( Z_1 \right)^2}{r_0} \]

\[ = \frac{2.31 \times 10^{-28} \text{ N} \cdot \text{m}^2}{0.205 \times 10^{-9} \text{ m}} \]

\[ = 1.10 \times 10^{-8} \text{ N} \]

(b) At the equilibrium separation distance the sum of attractive and repulsive forces is zero according to Equation 2.4. Therefore

\[ F_R = -F_A \]
The force of attraction between a divalent cation and a divalent anion is 1.67 x 10^{-8} \text{ N}. If the ionic radius of the cation is 0.080 nm, what is the anion radius?

Solution

To begin, let us rewrite Equation 2.15 to read as follows:

\[ r_0 = r_C + r_A \]

in which \( r_C \) and \( r_A \) represent, respectively, the radii of the cation and anion. Thus, this problem calls for us to determine the value of \( r_A \). However, before this is possible, it is necessary to compute the value of \( r_0 \) using Equation 2.14, and replacing the parameter \( r \) with \( r_0 \). Solving this expression for \( r_0 \) leads to the following:

\[
 r_0 = \sqrt{\frac{(2.31 \times 10^{-28} \text{ Nm}^2)(Z_C)(Z_A)}{F_A}}
\]

Here \( Z_C \) and \( Z_A \) represent charges on the cation and anion, respectively. Furthermore, inasmuch as both ion are divalent means that \( Z_C = +2 \) and \( Z_A = -2 \). The value of \( r_0 \) as determined as follows:

\[
 r_0 = \sqrt{\frac{(2.31 \times 10^{-28} \text{ Nm}^2)(+2)(-2)}{1.67 \times 10^{-8} \text{ N}}}
\]

\[
 = 0.235 \times 10^{-9} \text{ m} = 0.235 \text{ nm}
\]

Using the version of Equation 2.15 given above, and incorporating this value of \( r_0 \) and also the value of \( r_C \) given in the problem statement (0.080 nm) it is possible to solve for \( r_A \):

\[
 r_A = r_0 - r_C
\]
The net potential energy between two adjacent ions, $E_N$, may be represented by the sum of Equations 2.9 and 2.11; that is,

$$E_N = -\frac{A}{r} + \frac{B}{r + \frac{r_n}{2}}$$

(2.17)

Calculate the bonding energy $E_0$ in terms of the parameters $A$, $B$, and $n$ using the following procedure:

1. Differentiate $E_N$ with respect to $r$, and then set the resulting expression equal to zero, since the curve of $E_N$ versus $r$ is a minimum at $E_0$.

2. Solve for $r$ in terms of $A$, $B$, and $n$, which yields $r_0$, the equilibrium interionic spacing.

3. Determine the expression for $E_0$ by substitution of $r_0$ into Equation 2.17.

**Solution**

(a) Differentiation of Equation 2.17 yields

$$dE = A \frac{dr}{r} - B \frac{dr}{r + \frac{r_n}{2}}$$

$$dE = \sum \frac{\Delta r}{r} + \sum \frac{\Delta r}{r + \frac{r_n}{2}}$$

$$= \frac{A}{r} - \frac{nB}{r + \frac{r_n}{2}}$$

$$= 0$$

(b) Now, solving for $r$ ($= r_0$)

$$r_0 = \frac{A}{nB}$$

or

$$\frac{1}{1 - n}$$

$$\Delta = A \frac{1}{r_0^{n+1}}$$
Substitution for \( r_0 \) into Equation 2.17 and solving for \( E (= E_0) \) yields

\[
E_0 = - \frac{A}{0} + \frac{B}{0}
\]

\[
= - \frac{A}{0} \left[ 1 + \frac{B}{0} \right] \frac{A}{0} \frac{A}{0} \frac{A}{0} \frac{A}{0}
\]

For a Na\(^{+}\)--Cl\(^{-}\) ion pair, attractive and repulsive energies \( E_A \) and \( E_R \), respectively, depend on the distance between the ions \( r \), according to

\[
E_A = -1.436 \quad \frac{7.32 \times 10^{-6}}{r}
\]

For these expressions, energies are expressed in electron volts per Na\(^{+}\)--Cl\(^{-}\) pair, and \( r \) is the distance in nanometers. The net energy \( E_N \) is just the sum of the preceding two expressions.

(a) Superimpose on a single plot \( E_N \), \( E_R \), and \( E_A \) versus \( r \) up to 1.0 nm.

(b) On the basis of this plot, determine (i) the equilibrium spacing \( r_0 \) between the Na\(^{+}\) and Cl\(^{-}\) ions, and (ii) the magnitude of the bonding energy \( E_0 \) between the two ions.

(c) Mathematically determine the \( r_0 \) and \( E_0 \) values using the solutions to Problem 2.18, and compare these with the graphical results from part (b).

Solution

(a) Curves of \( E_A \), \( E_R \), and \( E_N \) are shown on the plot below.
(b) From this plot:

\[ r_0 = 0.24 \text{ nm} \]

\[ E_0 = 5.3 \text{ eV} \]
(c) From Equation 2.17 for $EN$

\[
A = 1.436 \\
B = 7.32 \times 10^6 \\
\therefore n = 8
\]

Thus,

\[
\frac{1}{1-n} \approx A \frac{\hat{e}}{\hat{e}(8)(7.32 \times 10^{-6})\hat{u}}
\]

\[
r_0 = \frac{\hat{e}nB}{\phi}
\]

\[
\frac{1}{1-8} \approx \frac{1.436}{1.436} \frac{\hat{e}(8)(7.32 \times 10^{-6})\hat{u}}{\hat{e}(8)(7.32 \times 10^{-6})\hat{u}} = 0.236 \text{ nm} = \hat{e}
\]

and

\[
E_0 = -\frac{\hat{e}nB}{\phi} = -\frac{1.436}{1.436} \frac{\hat{e}(8)(7.32 \times 10^{-6})\hat{u}}{\hat{e}(8)(7.32 \times 10^{-6})\hat{u}} = -5.32 \text{ eV}
\]
2.20 Consider a hypothetical $X^+Y^-$ ion pair for which the equilibrium interionic spacing and bonding energy values are 0.38 nm and $-5.37$ eV, respectively. If it is known that $n$ in Equation 2.17 has a value of 8, using the results of Problem 2.18, determine explicit expressions for attractive and repulsive energies $E_A$ and $E_R$ of Equations 2.9 and 2.11.

**Solution**

(a) This problem gives us, for a hypothetical $X^+Y^-$ ion pair, values for $r_0$ (0.38 nm), $E_0$ ($-5.37$ eV), and $n$ (8), and asks that we determine explicit expressions for attractive and repulsive energies of Equations 2.9 and 2.11. In essence, it is necessary to compute the values of $A$ and $B$ in these equations. Expressions for $r_0$ and $E_0$ in terms of $n$, $A$, and $B$ were determined in Problem 2.18, which are as follows:

\[
\frac{1}{1 - n} \quad A \quad r_0 = \frac{1}{nB} \quad \text{and} \quad E_0 = -\frac{A}{1 - n} + \frac{B}{1 - n}
\]

Thus, we have two simultaneous equations with two unknowns (viz. $A$ and $B$). Upon substitution of values for $r_0$ and $E_0$ in terms of $n$, the above two equations become

\[
\frac{1}{1 - 8} = \frac{1}{8} \quad A \quad \frac{1}{1 - 8} = \frac{1}{8} \quad A
\]

\[
0.38 \text{ nm} = \frac{1}{8}B = \frac{1}{8}B
\]

and

\[
-5.37 \text{ eV} = -\frac{A}{1 - 8} + \frac{B}{8(1 - 8)}
\]

\[
\frac{1}{1 - 8} \quad \frac{1}{1 - 8} \quad A \quad \frac{1}{1 - 8} \quad B
\]

\[
= -\frac{A}{1 - 8} + \frac{B}{8/7}
\]
We now want to solve these two equations simultaneously for values of A and B. From the first of these two equations, solving for \(A/8B\) leads to

\[
A = 8B(0.38 \text{ nm})^{-7}
\]

Furthermore, from the above equation the \(A\) is equal to

\[
A = 8B(0.38 \text{ nm})^{-7}
\]

When the above two expressions for \(A/8B\) and \(A\) are substituted into the above expression for \(E_0\) (\(5.37 \text{ eV}\)), the following results

\[
-5.37 \text{ eV} = -\frac{8B(0.38 \text{ nm})^{-7} + B}{0.38 \text{ nm}} = -\frac{7B}{(0.38 \text{ nm})^8}
\]

Or

\[
-5.37 \text{ eV} = -\frac{7B}{(0.38 \text{ nm})^8}
\]

Solving for \(B\) from this equation yields

\[
B = 3.34 \times 10^{-4} \text{ eV-nm}^8
\]
Furthermore, the value of $A$ is determined from one of the previous equations, as follows:

$$A = 8B(0.38 \text{ nm})^{-7} = (8)(3.34 \times 10^{-4} \text{ eV-nm}^8)(0.38 \text{ nm})^{-7}$$

$$= 2.34 \text{ eV-nm}$$

Thus, Equations 2.9 and 2.11 become

$$E_A = - \frac{3.34 \times 10^{-4}}{2r34}$$

$$ER = \frac{8}{r}$$

Of course these expressions are valid for $r$ and $E$ in units of nanometers and electron volts, respectively.

2.21 The net potential energy $E_N$ between two adjacent ions is sometimes represented by the expression

$$E_N = -Cr + D \exp(\frac{-\rho r}{\sigma})$$

in which $r$ is the interionic separation and $C$, $D$, and $\rho$ are constants whose values depend on the specific material.

(a) Derive an expression for the bonding energy $E_0$ in terms of the equilibrium interionic separation $r_0$ and the constants $D$ and $\rho$ using the following procedure:

(i) Differentiate $E_N$ with respect to $r$, and set the resulting expression equal to zero.

(ii) Solve for $C$ in terms of $D$, $\rho$, and $r_0$.

(iii) Determine the expression for $E_0$ by substitution for $C$ in Equation 2.18.

(b) Derive another expression for $E_0$ in terms of $r_0$, $C$, and $\rho$ using a procedure analogous to the one outlined in part (a).

Solution
(a) Differentiating Equation 2.18 with respect to \( r \) yields

\[
dE = \frac{\partial}{\partial r} (r \phi - D \exp(-\rho r))
\]

\[
dr = \frac{C}{r^2 \rho} - \frac{D \exp(-\rho r)}{\rho}
\]

At \( r = r_0 \), \( dE/dr = 0 \), and

\[
\frac{\partial}{\partial r} (r \phi - D \exp(-\rho r)) = 0
\]

Solving for \( C \) yields

\[
C = \frac{\rho \phi}{r_0^2 D \exp(-\rho r_0)}
\]

Substitution of this expression for \( C \) into Equation 2.18 yields an expression for \( E_0 \) as

\[
E_0 = -\frac{\rho}{r} + D \exp(-\rho r_0) \phi
\]
(b) Now solving for $D$ from Equation 2.18a above yields

$$D = \frac{C \rho \exp \left( \frac{\rho}{r_0} \right) \div \varnothing}{r_0^2}$$

Substitution of this expression for $D$ into Equation 2.18 yields an expression for $E_0$ as

$$E_0 = -r + \frac{\exp \left( \frac{-\rho}{r_0} \right) \div \varnothing}{C \div \varnothing}$$

$$= -C + C \rho \frac{r_0}{r_0^2}$$

$$C \alpha \rho \div E_0 = \frac{-r_0 \div \varnothing}{r_0 \div \varnothing - 1}$$
Primary Interatomic Bonds

2.22 (a) Briefly cite the main differences among ionic, covalent, and metallic bonding.
(b) State the Pauli exclusion principle.

Solution

(a) The main differences between the various forms of primary bonding are:

Ionic--there is electrostatic attraction between oppositely charged ions.

Covalent--there is electron sharing between two adjacent atoms such that each atom assumes a stable electron configuration.

Metallic--the positively charged ion cores are shielded from one another, and also "glued" together by the sea of valence electrons.

(b) The Pauli exclusion principle states that each electron state can hold no more than two electrons, which must have opposite spins.
2.23 Make a plot of bonding energy versus melting temperature for the metals listed in Table 2.3. Using this plot, approximate the bonding energy for molybdenum, which has a melting temperature of 2617°C.

Solution

Below is plotted the bonding energy versus melting temperature for these four metals. From this plot, the bonding energy for molybdenum (melting temperature of 2617°C) should be approximately 680 kJ/mol. The experimental value is 660 kJ/mol.

Secondary Bonding or van der Waals Bonding

2.24 Explain why hydrogen fluoride (HF) has a higher boiling temperature than hydrogen chloride (HCl) (19.4 vs. –85°C), even though HF has a lower molecular weight.

Solution

The intermolecular bonding for HF is hydrogen, whereas for HCl, the intermolecular bonding is van der Waals. Since the hydrogen bond is stronger than van der Waals, HF will have a higher melting temperature.
Mixed Bonding

2.25 Compute the %IC of the interatomic bond for each of the following compounds: MgO, GaP, CsF, CdS, and FeO.

Solution

The percent ionic character is a function of the electron negativities of the ions $X_A$ and $X_B$ according to Equation 2.16. The electronegativities of the elements are found in Figure 2.9.

For MgO, $X_{Mg} = 1.3$ and $X_O = 3.5$, and therefore,

$$\%IC = \frac{1 - \exp(-0.25)(3.5 - 1.3)\hat{e}}{1 - \hat{u}} \times 100 = 70.1\%$$

For GaP, $X_{Ga} = 1.8$ and $X_P = 2.1$, and therefore,

$$\%IC = \frac{1 - \exp(-0.25)(2.1 - 1.8)\hat{e}}{1 - \hat{u}} \times 100 = 2.2\%$$

For CsF, $X_{Cs} = 0.9$ and $X_F = 4.1$, and therefore,

$$\%IC = \frac{1 - \exp(-0.25)(4.1 - 0.9)\hat{e}}{1 - \hat{u}} \times 100 = 92.3\%$$

For CdS, $X_{Cd} = 1.5$ and $X_S = 2.4$, and therefore,

$$\%IC = \frac{1 - \exp(-0.25)(2.4 - 1.5)\hat{e}}{1 - \hat{u}} \times 100 = 18.3\%$$

For FeO, $X_{Fe} = 1.7$ and $X_O = 3.5$, and therefore,

$$\%IC = \frac{1 - \exp(-0.25)(3.5 - 1.7)\hat{e}}{1 - \hat{u}} \times 100 = 55.5\%$$
2.26 (a) Calculate %IC of the interatomic bonds for the intermetallic compound Al₆Mn. (b) On the basis of this result what type of interatomic bonding would you expect to be found in Al₆Mn?

Solution

(a) The percent ionic character is a function of the electron negativities of the ions $X_A$ and $X_B$ according to Equation 2.16. The electronegativities for Al and Mn (Figure 2.9) are 1.5 and 1.6, respectively. Therefore the percent ionic character is determined using Equation 2.16 as follows:

$$\%IC = 1 - \exp(-0.25)(1.6-1.5)^2 \cdot 100 = 0.25\%$$

(b) Because the percent ionic character is exceedingly small (0.25%) and this intermetallic compound is composed of two metals, the bonding is completely metallic.
Bonding Type-Material Classification Correlations

2.27 What type(s) of bonding would be expected for each of the following materials: solid xenon, calcium fluoride (CaF$_2$), bronze, cadmium telluride (CdTe), rubber, and tungsten?

Solution

For solid xenon, the bonding is van der Waals since xenon is an inert gas.

For CaF$_2$, the bonding is predominantly ionic (but with some slight covalent character) on the basis of the relative positions of Ca and F in the periodic table.

For bronze, the bonding is metallic since it is a metal alloy (composed of copper and tin).

For CdTe, the bonding is predominantly covalent (with some slight ionic character) on the basis of the relative positions of Cd and Te in the periodic table.

For rubber, the bonding is covalent with some van der Waals. (Rubber is composed primarily of carbon and hydrogen atoms.)

For tungsten, the bonding is metallic since it is a metallic element from the periodic table.
The chemical composition of the repeat unit for nylon 6,6 is given by the formula \( \text{C}_{12}\text{H}_{22}\text{N}_{2}\text{O}_{2} \). Atomic weights for the constituent elements are \( A_{\text{C}} = 12, A_{\text{H}} = 1, A_{\text{N}} = 14, \) and \( A_{\text{O}} = 16 \). According to this chemical formula (for nylon 6,6), the percent (by weight) of carbon in nylon 6,6 is most nearly: (A) 31.6\%  
(B) 4.3\%  
(C) 14.2\%  
(D) 63.7\%

**Solution**

The total atomic weight of one repeat unit of nylon 6,6, \( A_{\text{total}} \), is calculated as

\[
A_{\text{total}} = (12 \text{ atoms})(A_{\text{C}}) + (22 \text{ atoms})(A_{\text{H}}) + (2 \text{ atoms})(A_{\text{N}}) + (2 \text{ atoms})(A_{\text{O}})
\]

\[
= (12 \text{ atoms})(12 \text{ g/mol}) + (22 \text{ atoms})(1 \text{ g/mol}) + (2 \text{ atoms})(14 \text{ g/mol}) + (2 \text{ atoms})(16 \text{ g/mol}) = 226 \text{ g/mol}
\]

Therefore the percent by weight of carbon is calculated as

\[
\left( \frac{12 \text{ atoms}}{A_{\text{total}}} \right) \times 100 \text{ C(wt\%)} = \left( \frac{12 \text{ atoms}}{226 \text{ g/mol}} \right) \times 100 = 63.7\%
\]

which is answer D.
Which of the following electron configurations is for an inert gas? (A)

1s^22s^22p^63s^23p^6

(B) 1s^22s^22p^63s^2

(C) 1s^22s^22p^63s^23p^64s^1

(D) 1s^22s^22p^63s^23p^63d^24s^2

Solution

The correct answer is A. The 1s^22s^22p^63s^23p^6 electron configuration is that of an inert gas because of filled 3s and 3p subshells.
2.3FE
2.4FE

What type(s) of bonding would be expected for bronze (a copper-tin alloy)?

(A) Ionic bonding
(B) Metallic bonding
(C) Covalent bonding with some van der Waals bonding
(D) van der Waals bonding

Solution

The correct answer is B. For bronze, the bonding is metallic because it is a metal alloy.
2.5FE

What type(s) of bonding would be expected for rubber?

(A) Ionic bonding
(B) Metallic bonding
(C) Covalent bonding with some van der Waals bonding
(D) van der Waals bonding

Solution

The correct answer is C. For rubber, the bonding is covalent with some van der Waals bonding. (Rubber is composed primarily of carbon and hydrogen atoms.)
2.6FE
